tuning has been the predominant method for many years, most servo drives now incorporate functions that will automatically tune the system.

### **Auto tuning methods for servo drives - Motion Control Tips**

Servo tuning need not be more difficult than other typical motion tasks such as sizing a motor. There are a number of standard manual methods available, two of which, step-response tuning and zone-based tuning, are discussed in this article.

Tuning Guide Overview. This section covers tuning the velocity and position loops in the AKD. Servo tuning is the process of setting the various drive coefficients that are needed for the drive to optimally control the servo motor for your application. There are different ways to tune, and several are covered here.

Servo update time is the time interval between the calculations for command (C) minus feedback (F) to give error (E). In other words, it is how often a correction (E) is calculated. Update times vary from microseconds up to 16 ms (milliseconds) for most controllers.

### **SERVO BASICS FOR THE LAYMAN**

Closed-loop servo systems require settings for the control loop gain and filter values to make sure that the load accurately follows the desired input-command signal. The process of adjusting and refining the gain and filter configuration is called tuning. Appropriate tuning settings depend heavily upon the system characteristics.

## **Tuningless Features for Kinetix 5500 and Kinetix 5700 ...**

Scales introduce several variables into servo tuning. The motor encoder is used to control the velocity loop and the scale is used to control the positioning loop. There is always a lag between the motor encoder feedback and the scale feedback. That lag needs to be accounted for in the tuning.

Here is the basic approach used with step-response motor tuning: Initialize the I & P terms to zero, and set the D term to a small non-zero value Increase P from zero until the system overshoots and shows an under-damped response Increase D until the oscillation is 'critically damped' Repeat from ...

### **Servo Motor Tuning - A Deep Dive**

Servo tuning can be achieved through a variety of procedures, but the most common method is to begin by increasing  $K_p$  until the system overshoots the target (the system is underdamped). Then  $K_d$  is increased until the system becomes critically damped (a balance between fast response and low overshoot).
